

Finite State Automata

Natalie Parde

UIC CS 421

What are finite state automata?

- **Computational models that can generate regular languages** (such as those specified by a regular expression)
- Also used in other NLP applications that function by **transitioning between finite states**
 - Dialogue systems
 - Morphological parsing
- Singular: Finite State Automaton (FSA)
- Plural: Finite State Automata (FSAs)

Key Components

- Finite set of states
 - Start state
 - Final state
- Set of transitions from one state to another

How do FSAs work?

- For a given sequence of items (characters, words, etc.) to match, **begin in the start state**
- **If the next item** in the sequence **matches a state that can be transitioned to** from the current state, **go to that state**
- **Repeat**
 - If no transitions are possible, **stop**
 - If the state you stopped in is a final state, **accept the sequence**

FSAs are often represented graphically.

- Nodes = states
- Arcs = transitions

What do we know about this FSA?

- Five states
 - q_0 is the start state
 - q_4 is the final (accept) state
- Five transitions
- Alphabet = $\{a, b, !\}$

Formal Definition

- A finite state automaton can be specified by enumerating the following properties:
 - The set of states, Q
 - A finite alphabet, Σ
 - A start state, q_0
 - A set of accept/final states, $F \subseteq Q$
 - A transition function or transition matrix between states, $\delta(q, i)$
- $\delta(q, i)$: Given a state $q \in Q$ and input $i \in \Sigma$, $\delta(q, i)$ returns a new state $q' \in Q$.

Example: FSA for Dollar Amounts

State transitions in FSAs can be represented using tables.

Next Item in Sequence					
Currently in State		b	a	!	<end>
	q_0				
	q_1				
	q_2				
	q_3				
	q_4				

State transitions in FSAs can be represented using tables.

		Next Item in Sequence			
		b	a	!	<end>
Currently in State	q ₀	q ₁			
	q ₁				
	q ₂				
	q ₃				
	q ₄				

Go to State

Accept! →

State transition tables simplify the process of determining whether your input will be accepted by the FSA.

- For a given sequence of items to match, **begin in the start state** with the first item in the sequence
- **Consult the table** ...is a transition to any other state permissible with the current item?
- If so, **move to the state indicated by the table**
- If you make it to the end of your sequence and to a final state, **accept**

Formal Algorithm

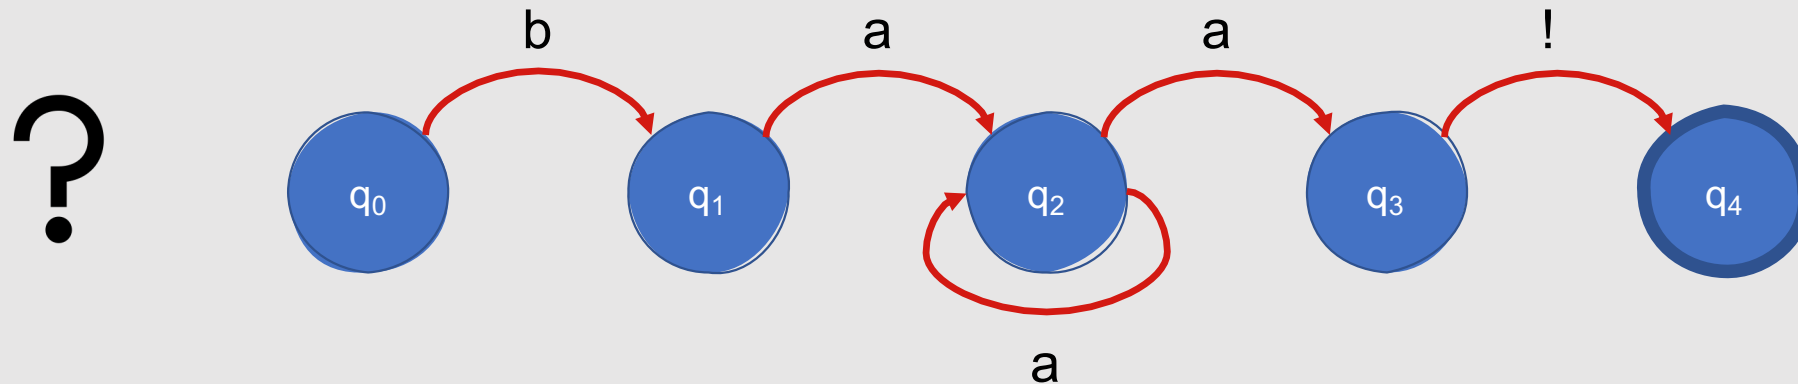

```
index ← beginning of sequence
current_state ← initial state of FSA
loop:
    if end of sequence has been reached:
        if current_state is an accept state:
            return accept
        else:
            return reject
    else if transition_table[current_state, sequence[index]] is empty:
        return reject
    else:
        current_state ← transition_table[current_state, sequence[index]]
        index ← index + 1
end
```

Deterministic vs. Non-Deterministic FSAs

Deterministic FSA: At each point in processing a sequence, there is one unique thing to do (no choices!)

Non-Deterministic FSA: At one or more points in processing a sequence, there are multiple permissible next steps (choices!)

Deterministic or Non-Deterministic?

Deterministic or Non-Deterministic?

Deterministic!

?

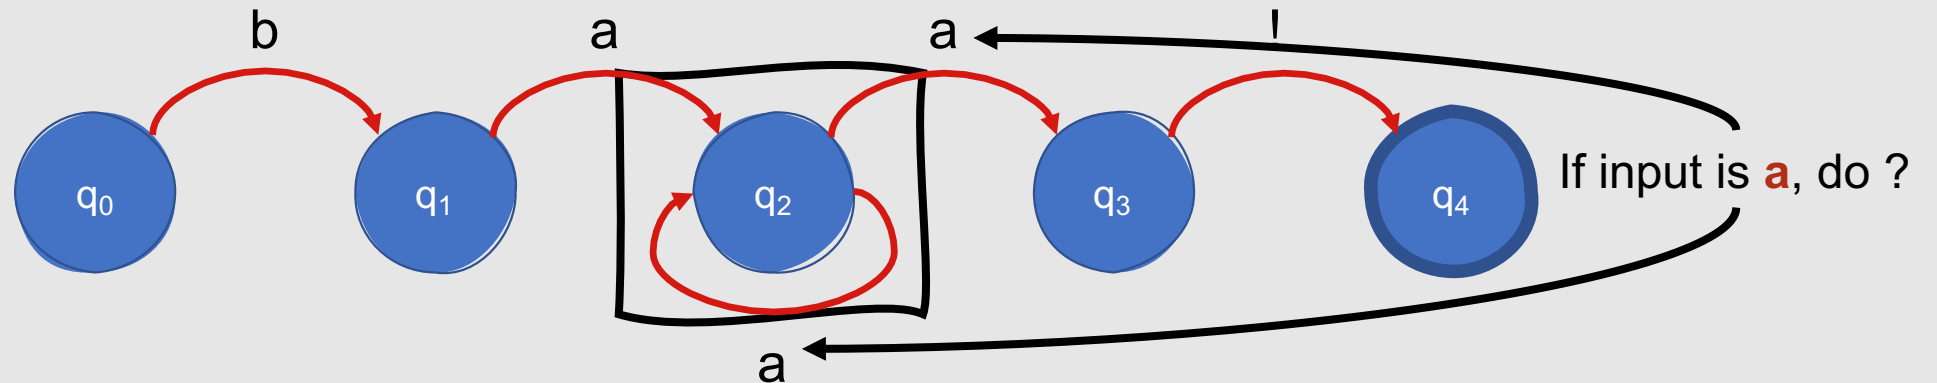

Deterministic or Non-Deterministic?

Deterministic!

Non-Deterministic!

Every non-deterministic FSA can be converted to a deterministic FSA.

- This means that both are equally powerful!
- Deterministic FSAs can accept as many languages as non-deterministic ones

Non-Deterministic FSAs: How to check for input acceptance?

- Two approaches:
 1. Convert the non-deterministic FSA to a deterministic FSA and then check that version
 2. Manage the process as a state-space search

Non-Deterministic FSA Search Assumptions

There exists at least one path through the FSA for an item that is part of the language defined by the machine

Not all paths directed through the FSA for an accept item lead to an accept state

No paths through the FSA lead to an accept state for an item not in the language

Non-Deterministic FSA Search Assumptions

- **Success:** Path is found for a given item that ends in an accept
- **Failure:** All possible paths for a given item lead to failure

Example: Non-Deterministic FSA Search

Test Input: baaa!

Example: Non-Deterministic FSA Search

Test Input: **b**aaa!

Example: Non-Deterministic FSA Search

Test Input: **b**aaa!

Example: Non-Deterministic FSA Search

Test Input: **baaa!**

Example: Non-Deterministic FSA Search

Test Input: **baaa!** 😊

Non-Deterministic FSA Search

- States in the search space are pairings of sequence indices and states in the FSA
- By keeping track of which states have and have not been explored, we can systematically explore all the paths through an FSA given an input

Compositional FSAs

- You can apply set operations to any FSA
 - Union
 - Concatenation
 - Negation
 - For non-deterministic FSAs, first convert to a deterministic FSA
 - Intersection
- To do so, you may need to utilize an ϵ transition
 - ϵ transition: Move from one state to another without consuming an item from the input sequence

Summary: Finite State Automata

- FSAs are computational models that describe regular languages
- To determine whether an input item is a member of an FSA's language, you can process it sequentially from the start to (hopefully) the final state
- State transitions in FSAs can be represented using tables
- FSAs can be either deterministic or non-deterministic
